Tree Species Diversity and Architecture Determine Spider Abundance in a Forest **Diversity Experiment**

Elizabeth Butz¹, Lauren Schmitt¹, John Parker², and Karin Burghardt^{1,2} ¹University of Maryland, College Park, MD, ²Smithsonian Environmental Research Center, Edgewater, MD

Introduction

In forest ecosystems, trees are an important habitat for predatory arthropods performing important ecosystem roles such as regulating herbivorous insect population levels. The few existing studies on higher trophic levels in arboreal habitats have found that spider abundances increase with more complex tree architecture, such as leaf density^{1,2}. Here, we ask:

- 1) Are spider abundances influenced by tree species identity or diversity level?
- 2) How do habitat covariates influence spider abundances?
- 3) How does the influence of these variables on spider abundances change across summer?

Methods

We sampled at the "BiodiversiTREE" experimental site in Edgewater, MD in June and August 2021. We sampled 540 focal trees representing 15 species across plots with a diversity of 1, 4, and 12 species. For each tree, along with plot diversity level and focal tree species identity, we recorded:

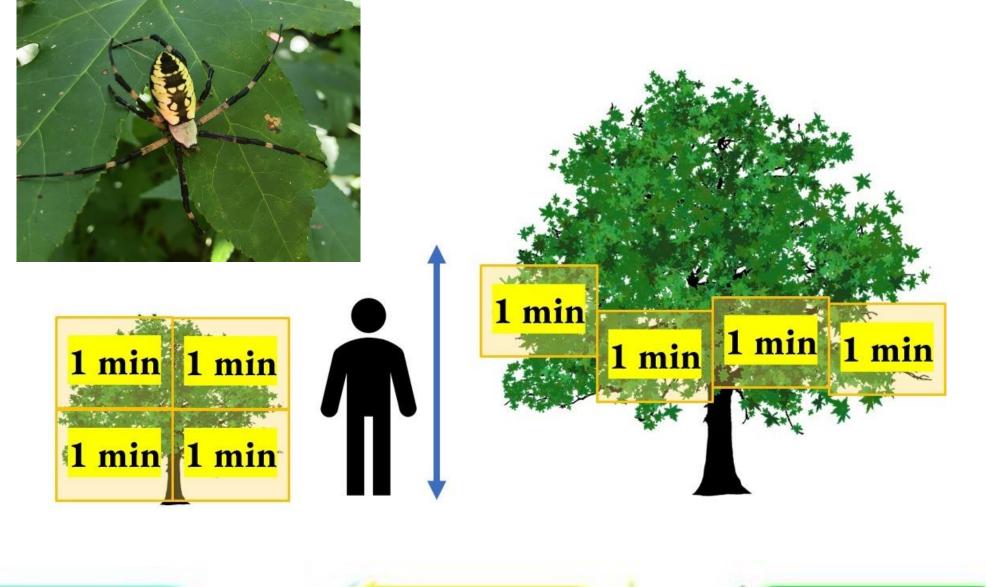

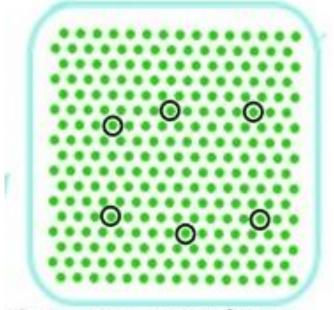

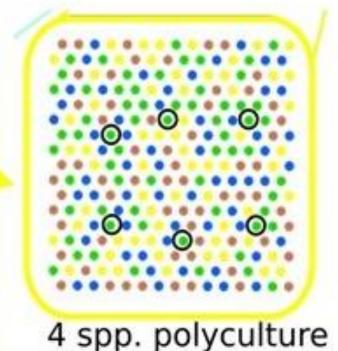

Spider abundance **Tree Height**

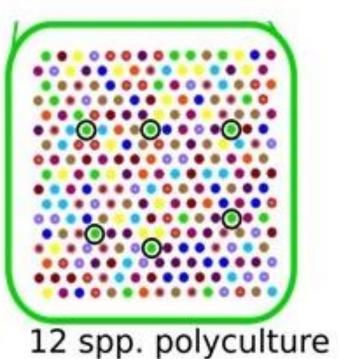

Canopy Cover

Data were log-transformed and analyzed using a linear mixed model in R using a random effect structure^{3,4}. Data were analyzed across the entire summer and then individually for June and August.

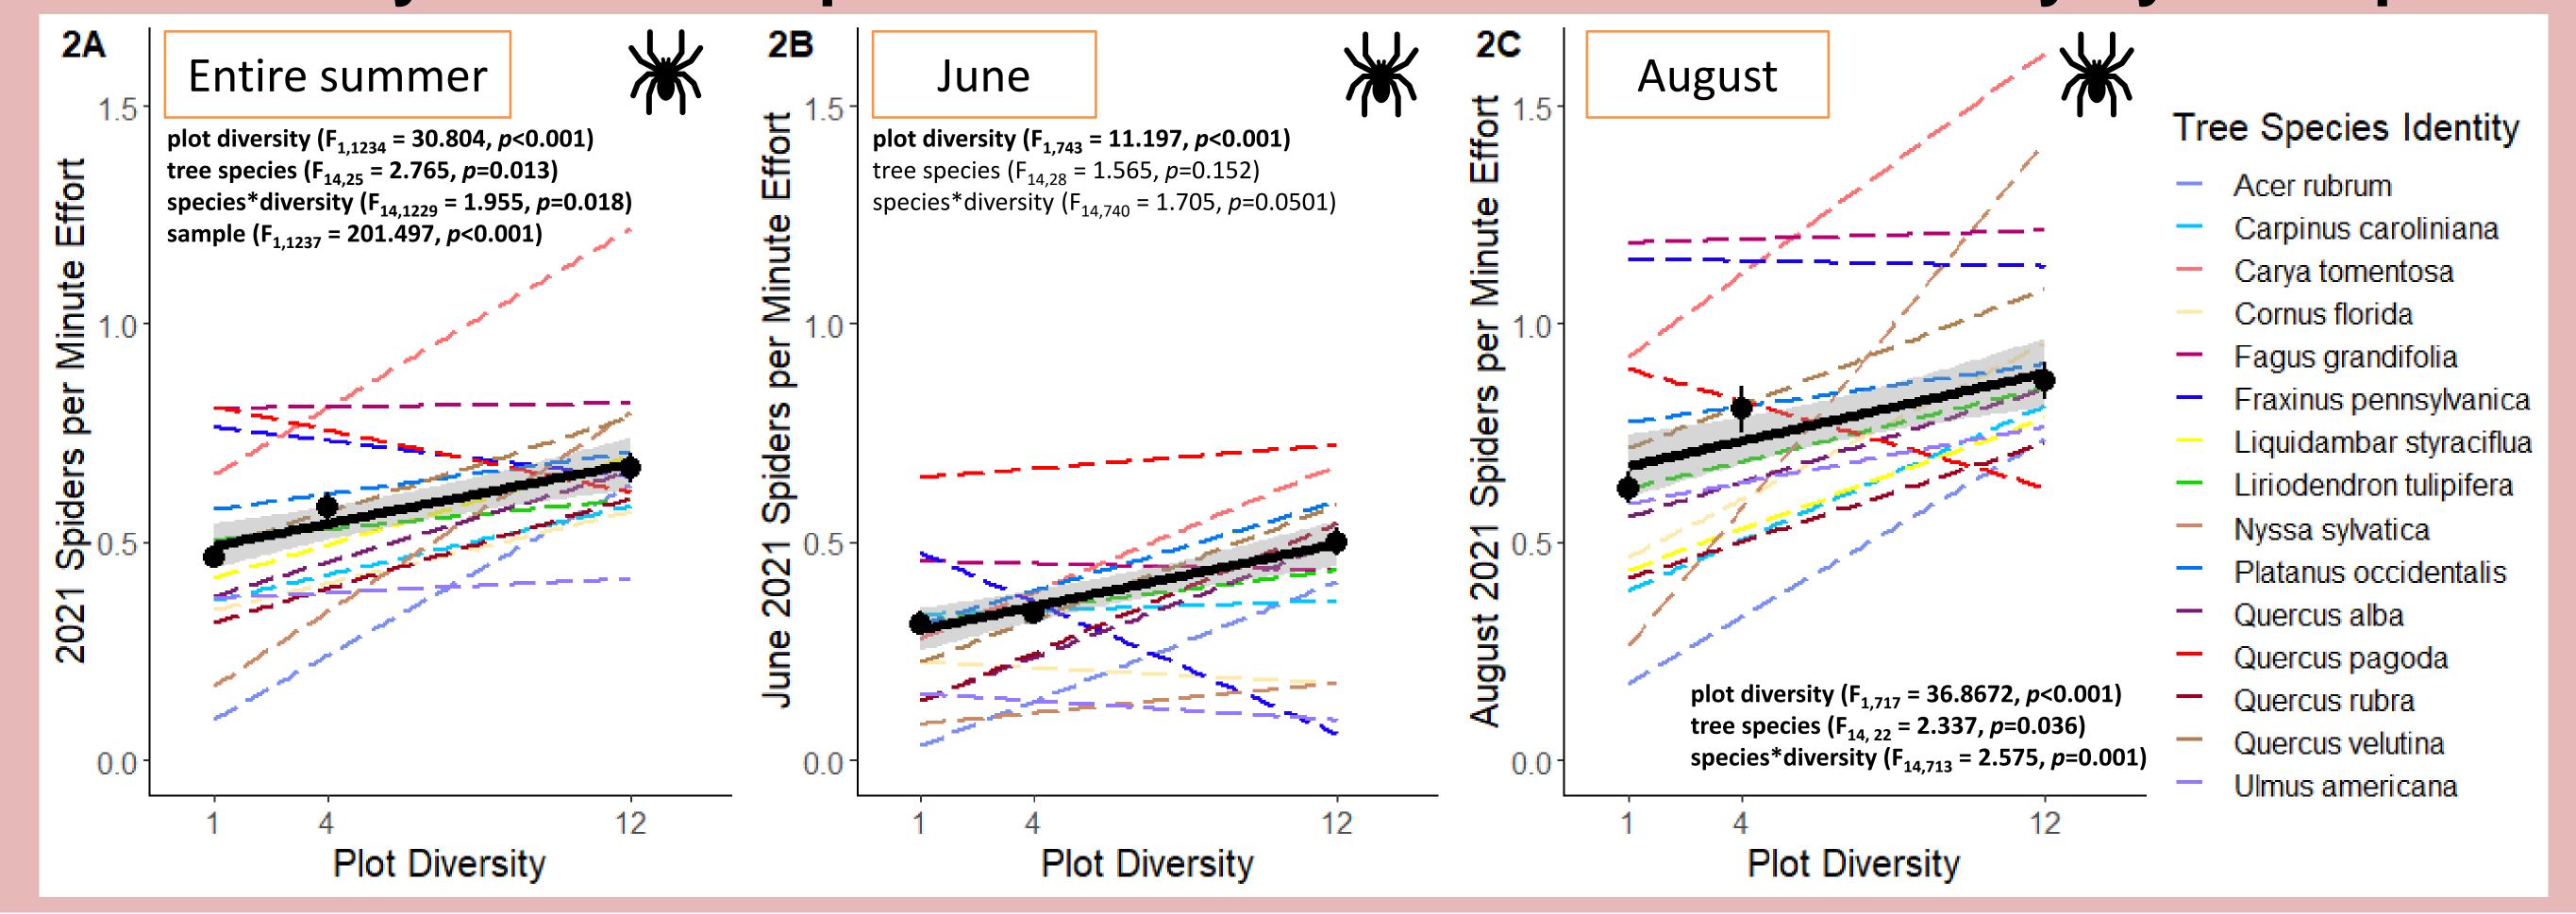

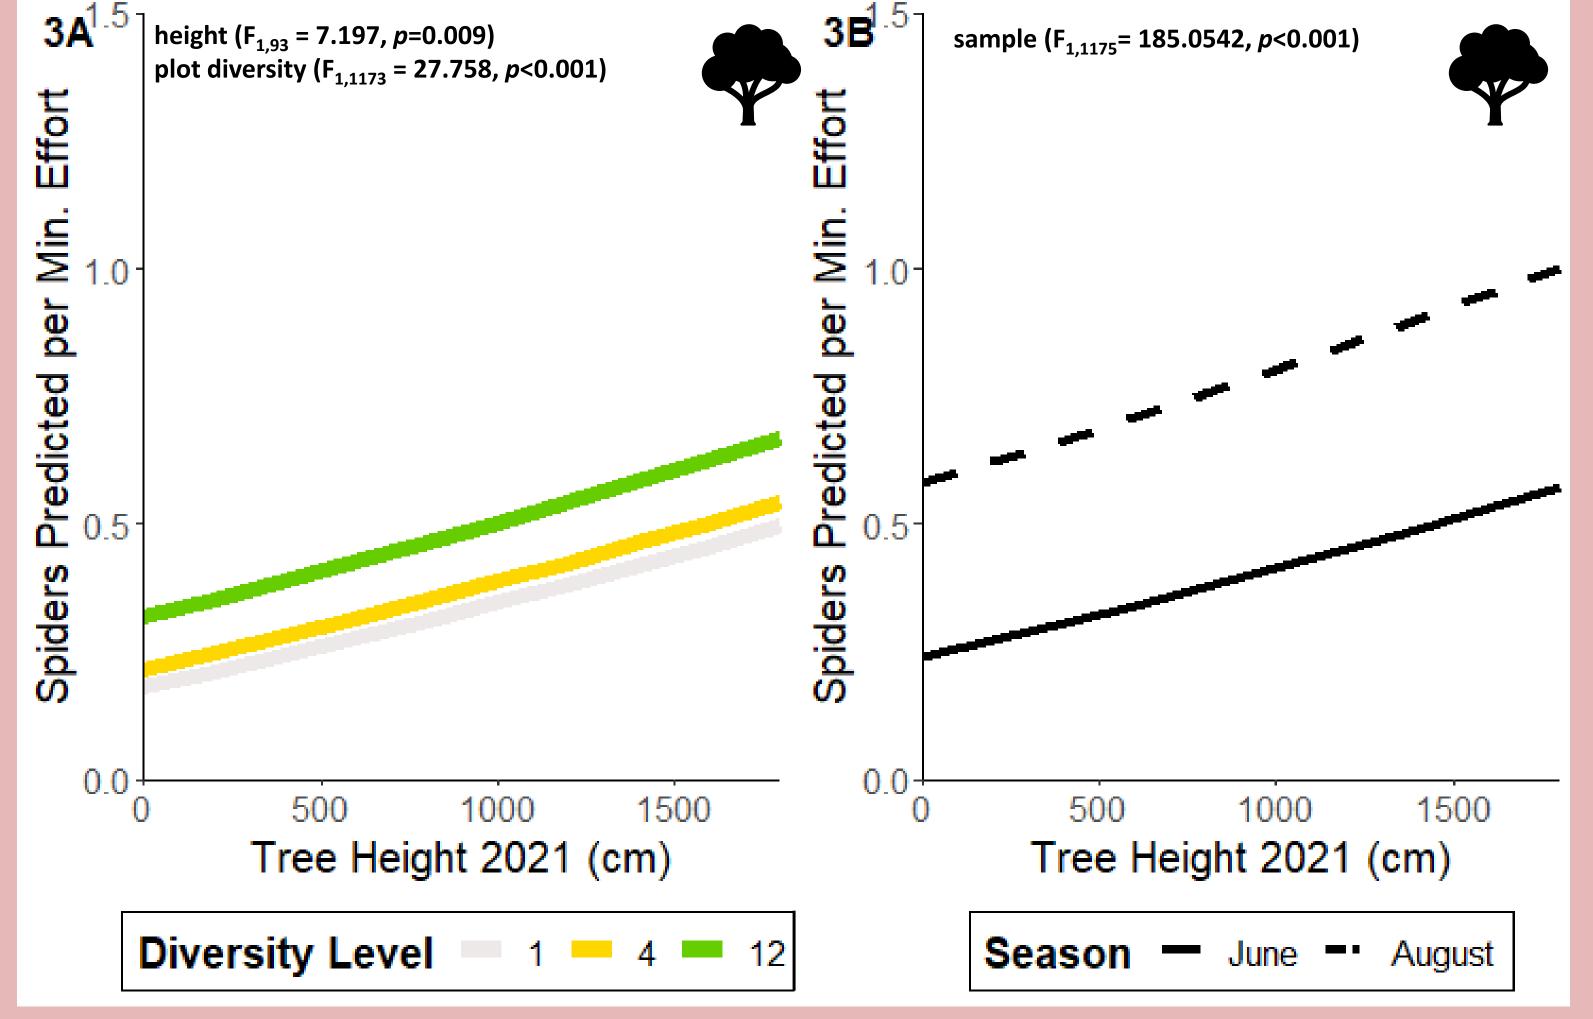

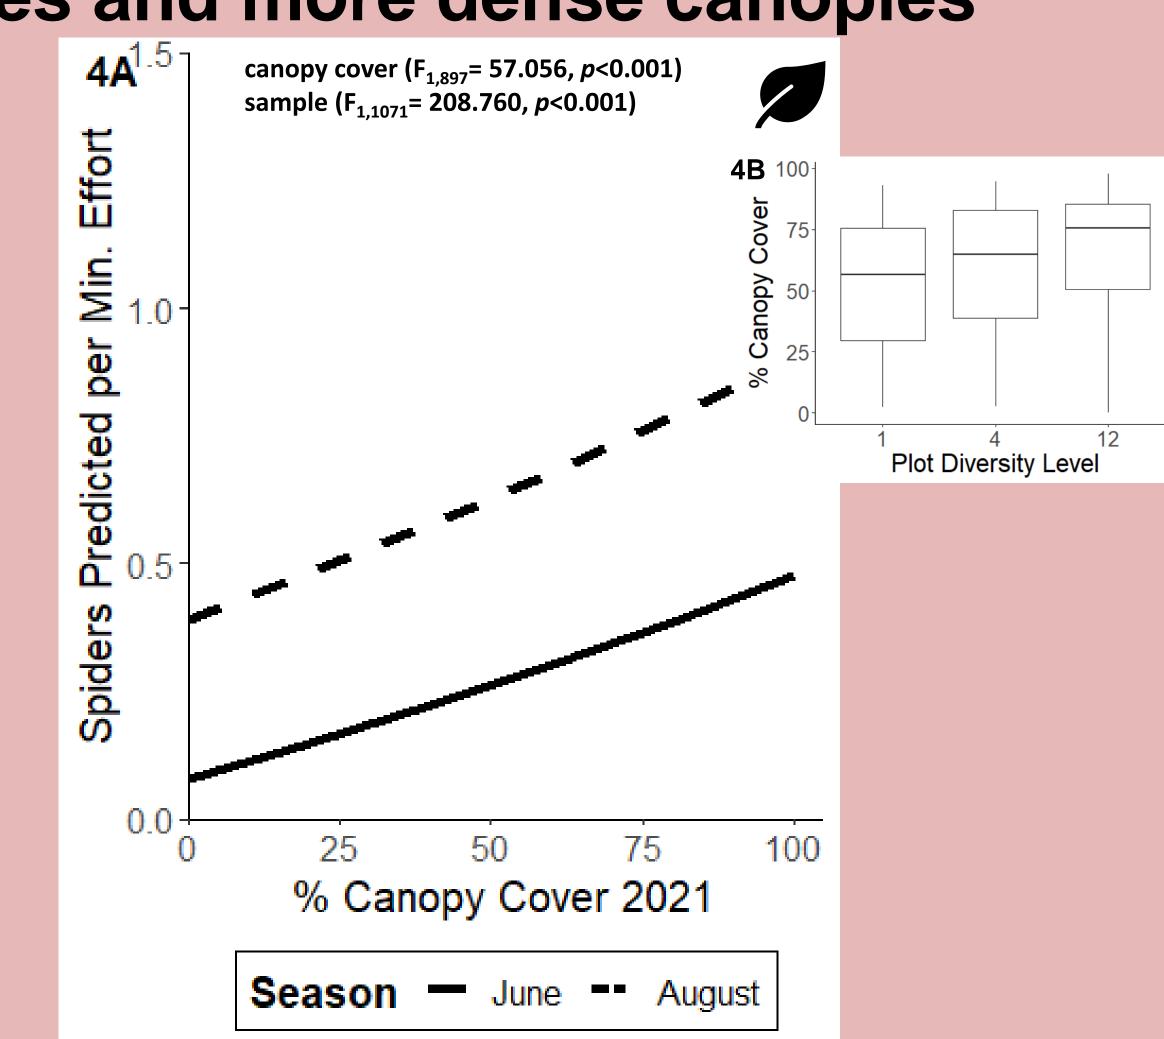

Results

Plot diversity increases spider abundance and abundances vary by tree species

Spider abundances increase with taller trees and more dense canopies

Discussion

Spider abundances vary based on species identity and are higher in diverse plots and later in summer. There are several potential explanations:

- Spiders may find higher herbivore abundances in more diverse plots (e.g., increased prey)
- Spiders may increase throughout summer due to life cycle differences across the summer (e.g., traveling to the forest floor in order to mate)
- Spiders are more abundant in taller trees and with greater canopy coverage because of the increased niches available (e.g., more foliage for ambush spiders as well as branches for web-builders)

Next steps include including spider functional guild in the analysis in order to determine how species diversity is influenced by our habitat covariates.
